

# **Course Learning Outcomes for Unit III**

Upon completion of this unit, students should be able to:

- 3. Apply time value of money techniques to various pricing (valuation) and budgeting problems.
  - 3.1 Explain compounding and discounting to calculate future and present values.
  - 3.2 Determine annuities from a single sum.
  - 3.3 Demonstrate how to apply time value of money concepts to complex cash streams.

### **Reading Assignment**

Chapter 5: Time Value of Money - The Basics, pp. 126-150

Chapter 6: The Time Value of Money - Annuities and Other Topics, pp. 156-179

### **Unit Lesson**

Creating value hinges on timing of cash flows. In finance, understanding time value of money is critical to value creation because cash flows resolve when an organization can create value. Discounting and compounding are key ingredients for looking at how time affects value creation. Take the case of Brite Phuteur, who has started a career and needs a new car.

Phuteur has looked at different cars and has a good idea what he wants to buy. After looking at several dealerships, Phuteur noted pricing did not necessarily line up with his ideas about paying a fair price for the value he thought he would receive. Phuteur found dealerships varied their pricing on identical cars.

Despite not understanding price variances between dealers, Phuteur set aside money from his pay each pay period for a good down payment. Interest rates on savings at his local bank amounted to roughly 2%. If Phuteur set aside \$100 a month at the end of the year, he wanted to know how much he would have after earning interest. This scenario is Phuteur's first experience where he needed to understand compounding. Phuteur asked his banker, Cash Kownter, for help. Kownter explained that compound interest adds interest earned to principal used when calculating future interest. For example, Phuteur started by putting \$1,000 in savings in his bank, which pays 2% interest a year compounded monthly. Since Phuteur's local bank figures interest monthly, his monthly interest rate is just .16667% but compounds each of the 12 months during the year. Kownter showed Phuteur a formula to calculate the amount he would have by year's end. A general future value formula solves this calculation as follows (Titman, Keown, & Martin, 2014, p. 130):

 $FV = PV(1 + i)^n$ , where FV equals future value, PV equals present value, i equals an interest rate, and n is the number of periods. Applying this equation, Phuteur can substitute his numbers into the formula as follows:

FV = \$1,000(1 + .16667%)<sup>12</sup> Thus, FV = \$1,000(1.0016667)<sup>12</sup> FV = \$1,020.18 Phuteur observed he has more than simple interest, which simply adds 2% to \$1,000, which only accounts for \$1,020.00 of the \$1,020.18 earned. Kownter showed Phuteur how to solve this problem in Excel as follows:

fx =FV(2%	=FV(2%/12,12,,-1000) Function Arguments		Monthly intere 2% divided by	est is .1667% or 7 12 months.	8 23		
FV	FV			1			
	Rate	2%/12	=	= 0.001666667			
	Nper	12	=	= 12			
	Pmt		= number				
	Pv -1000		= -1000				
_	Туре		=	= number			
Returns the	<ul> <li>= 1020.184356</li> <li>Returns the future value of an investment based on periodic, constant payments and a constant interest rate.</li> <li>Pv is the present value, or the lump-sum amount that a series of future payments is worth now. If omitted, Pv = 0.</li> </ul>						
Formula res	sult = 1020.184356 <u>s function</u>	Value at more tha simple in	end of year is n principal and nterest.	ок	Cancel		

Despite compound interest exceeding simple interest, Phuteur noted the amount earned is not much more than he put in his savings to start. Phuteur asked Kownter what he would earn if he left the money in the bank for five years. Kownter changed his calculation as follows:

```
FV = $1,000(1 + .16667%)<sup>12</sup>
Thus,
FV = $1,000(1.0016667)<sup>12*5</sup>
FV = $1,105.08
```

Again Kownter made the calculation in Excel as follows:

=FV(2%/12,12*5,,-1000) Function Arguments		Notice Kownter multiplied 12 months by 5 years, which equals 60 months.				
FV Rate 2%/12 Nper 12*5 Pmt Pv -1000 Type		0.001666667 = 60 = number = -1000 = number				
= 1105.078927 Returns the future value of an investment based on periodic, constant payments and a constant interest rate. Nper is the total number of payment periods in the investment. Formula result = 1105.078927						
Help on this function OK Cancel						

This time, Phuteur noted more interest earned by comparing \$1,105.08 with \$1,020.00 principal plus simple interest. Phuteur earned \$85.08 in interest compared with just \$.18 for just a year. Phuteur inferred the more periods the greater the interest earned. Kownter explained compounding calculates interest on interest each period. Instead of simply computing interest on \$1,000.00, compounding recalculates interest each period (in this case 60 periods), which grows interest earned.

Although compound interest showed a nice improvement in interest earned, Phuteur wondered what he could earn if he also saved \$100 a month. Kownter told Phuteur, "Now you are talking about an annuity." Kownter explained an annuity is a series of equal payments for a specific time. Again, Kownter showed Phuteur how to calculate compound interest as follows:

$$FV_n = PMT(1 + i)^{n-1} + PMT(1 + i)^{n-2}... + PMT(1 + i)^1 + PMT(1 + i)^0$$

Alternatively, one can apply a future value annuity factor (FVA) to an annuity payment (PMT) using the formula as follows:

$$FVA = FVA_n = \left[\frac{(1+i)^{n}-1}{i}\right]$$

Applying this factor to the payment results in the following formula:

$$FV_n = PMT FV_n = PMT \left[\frac{(1+i)^n - 1}{i}\right]$$

Using \$100 a month savings deposit Kownter filled in this formula as follows:

```
\begin{aligned} & \mathsf{FVA} = [(1.001667)^{60}/.001667] \\ & \mathsf{FVA} = 63.04734 \\ & \mathsf{FV}_{60} = 100(63.04734) \\ & \mathsf{FV}_{60} = 6304.74 \end{aligned}
```

Alternatively, Kownter again substitutes in Excel as follows:

£ =FV(2%/12,12*5,-100)					
Function Arguments					
FV					
Rate	2%/12 💽 = 0.001666667				
Nper	12*5 🛋 = 60				
Pmt	-100 🛋 = -100				
Pv	🐹 = number				
Туре	🔝 = number				
= 6304.735592 Returns the future value of an investment based on periodic, constant payments and a constant interest rate.					
Rate is the interest rate per period. For example, use 6%/4 for quarterly payments at 6% APR.					
Formula result = \$6,304.74					
Help on this function	OK Cancel				

With both an initial deposit of \$1,000 in savings and an added \$100 a month, the result is as follows:

fx =FV(2%/12,12*5,-100,-1000)					
Function Arguments	8 23				
FV					
Rate	2%/12 = 0.001666667				
Nper	12*5 💽 = 60				
Pmt	-100				
Pv	-1000 = -1000				
Туре	= number				
= 7409.814518 Returns the future value of an investment based on periodic, constant payments and a constant interest rate. <b>Rate</b> is the interest rate per period. For example, use 6%/4 for quarterly payments at 6% APR.					
Formula result = \$7,409.81 Help on this function Cancel					

Phuteur felt better about saving for a down payment after calculating what he would have. Interest earned over five years is \$409.82 (\$105.08 plus \$304.74) plus principal of \$7,000 (\$1,000 plus \$6,000 or 60 payments times \$100). Compound interest allowed Phuteur to grow his money by adding interest on interest earned.

Besides resolving he could have a large down payment, Phuteur still needed to know what he would have to pay monthly on a car. Phuteur looked at several cars on the Internet and settled on a car that sells for \$25,000. Phuteur figured he would have a balance of \$17,509.81 (\$25,000 minus \$7,409.81) he would need to finance. Phuteur asked at the bank what rate he would have to pay on a car loan. The bank gave Phuteur a rate of 4.5%. Phuteur asked Kownter how he could calculate his payments. Kownter responded by saying it might benefit Phuteur to prepare an amortization table to break down his payments between principal and interest.

Kownter explained first Phuteur would need to calculate his payment. Kownter showed Phuteur how to calculate his payment in Excel as follows:

Function Arguments	Bank rate 4.5% divided by 12 months equals .375% monthly.				
Rate	4.5%/12 = 0.00375				
Nper	5*12 💽 = 60 Original				
Pv	-17590.19 = -17590.19 principal				
Fv	= number				
Туре	= number				
= 327.9342506 Calculates the payment for a loan based on constant payments and a constant interest rate. <b>Rate</b> is the interest rate per period for the loan. For example, use 6%/4 for quarterly payments at 6% APR. Calculated					
Formula result = \$327.9	3 payment.				
Help on this function OK Cance					

Kownter assumed a normal five year loan and interest would compound monthly. Using a variant of the formula used to calculate the future value (FV) Kownter calculated Phuteur's payment as follows:

$$\mathsf{PV}_{\mathsf{n}} = \mathsf{PMT} \ PV = PMT \left[ \frac{\frac{1}{(1+\frac{1}{m})^{n \times m}}}{i/m} \right]$$

Substituting the above information Kownter solved the equation for the payment.

$$\$17,509.81 = \mathsf{PMT}\left[\frac{\frac{1}{(1+\frac{045}{12})^{5\times 12}}}{.045/12}\right]$$

\$17,509.81 = PMT(53.63938) PMT = \$17,590.81/\$53.64197 PMT = 327.93

Kownter prepared the following amortization table in Excel:

			Principal		
	_	Payments	Interest	Reduction	Principal
Original balance					\$17,590.19
Payment	1	327.93	65.96	261.97	17,328.22
Payment	2	327.93	64.98	262.95	17,065.27
Payment	3	327.93	63.99	263.94	16,801.33
Payment	4	327.93	63.00	264.93	16,536.40
Payment	5	327.93	62.01	265.92	16,270.47
Payment	55	327.93	7.28	320.65	1,621.39
Payment	56	327.93	6.08	321.85	1,299.53
Payment	57	327.93	4.87	323.06	976.47
Payment	58	327.93	3.66	324.27	652.20
Payment	59	327.93	2.45	325.49	326.71
Payment	60	327.93	1.23	326.71	0.00
		19,676.06	2,085.87	17,590.19	

With Kownter's table, Phuteur had an idea what interest and principal he would have to pay each month. Payments for 60 months is an annuity because they are equal for a set time. Phuteur noticed early payments had higher interest as part of payments, but later payments included more principal.

Because Kownter based payments on suggested retail price as suggested by the manufacturer, Phuteur wondered if he could buy his car for less. Phuteur began looking at current prices to see what different dealers offer. In today's prices, a similar car sold for \$21,500. Kownter helped Phuteur explained to Kownter how discounting the payments based on inflation rate of 2% might give him a better idea of the value today. Kownter first discounted the \$7,409.19 down payment to express it in today's dollars as follows:

Function Argum PV Monthly interest rate based on inflation rate.				
	Rate	2%/12 = 0.001666667		
	Nper	60 💽 = 60		
	Pmt	🐹 = number		
Down	Fv Fv	-7409.19 🛋 -7409.19		
payment	Туре	🐹 = number		
= 6704.670429 Returns the present value of an investment: the total amount that a series of future payments is worth now. <b>Rate</b> is the interest rate per period. For example, use 6%/4 for quarterly payments at 6% APR.				
Formula result = \$6,704.67 Help on this function Value of down payment today based on expected inflation. OK Cancel				

Kownter also solves for present value using the following formula:

```
\begin{split} \mathsf{PV} &= \mathsf{FVx1}/(1+i)^n \text{ or } \mathsf{PV}(1+i)^{-n} \\ \text{In Phuteur's case substituting the values looks like the following:} \\ \mathsf{PV} &= \$7,409.19 \times 1/(1+.00166667)^{60} \\ \mathsf{PV} &= \$7,409.19 \times 1/(1.01004) \\ \mathsf{PV} &= \$7,409.19 \times .90491 \\ \mathsf{PV} &= \$6,704.67 \end{split}
```

Next, Kownter calculated the present value of the payments Phuteur would have to make as follows:

Function Argume	Argume Monthly interest rate based on inflation rate.				
	Rate	= 0.001666667			
Monthly	Nper	60 💽 = 60			
payments	Pmt	-327.93 📧 = -327.93			
<u> </u>	Fv	🐹 = number			
	Туре	🐹 = number			
= 18709.17898 Returns the present value of an investment: the total amount that a series of future payments is worth now. <b>Rate</b> is the interest rate per period. For example, use 6%/4 for quarterly payments at 6% APR.					
Formula result = \$18,709.18 Value of monthly payments based on expected inflation. Help on this function OK Cancel					

Combining the down payment and interest payments Kownter found the value today is as follows:

Function Arguments			? ×		
PV			]		
Rate	2%/12	=	0.001666667		
Nper	5*12	=	60		
Pmt	-327.93	=	-327.93		
Fv	-7409.19	=	-7409.19		
Туре		=	number		
= 25413.84941 Returns the present value of an investment: the total amount that a series of future payments is worth now. <b>Rate</b> is the interest rate per period. For example, use 6%/4 for quarterly payments at 6% APR.					
Formula result = \$25,413.85	Combined present value of payment of \$6,704.67 plus monthly payments of \$18,7	do 09	.18. OK Cancel		

Comparing the \$25,413.85 with what Phuteur projected five years from now it appears \$25,000 is a fair price. Remember, however, Phuteur found one dealer selling the car he wanted for \$21,500 at today's prices. This price suggests the \$25,000 price in five years is too high, and Phuteur might well do better than the price Kownter used to calculate future payments. Assuming \$25,000 is more than Phuteur would have to pay in five years, he likely will have lower payments based on dealer price variation. This revelation excited Phuteur about saving for his new car.

In summary, compounding cash flows results in future values, while discounting cash flows, brings future cash flows back to today's dollars for the sake of comparison. Some cash streams are complex and have both—a single sum plus an annuity, or series of equal payments for a set time. Phuteur benefited from doing his homework and reaching out to his friend at the bank. Phuteur did a good job with his homework and is now ready to buy a car when the time comes.
